

AI Tools Used, Examples of My Own Judgement, Reflection

AI Tools Used

I used **ChatGPT** as a development and problem-solving assistant while building the Fulfillment Hub application.

I used AI mainly for:

- Breaking down the business problem into practical operational modules.
- Planning the application structure and database tables.
- Generating and refining Python, Streamlit and SQLite code.
- Debugging errors during development.
- Improving the user interface and navigation.
- Reviewing the application against the take-home task requirements.
- Creating and refining the README documentation.

I did not rely on AI alone for the final implementation. I manually tested the application and made changes based on the actual workflow and my understanding of the task.

Examples of My Own Judgement

1. Order Workflow

During development, AI suggested changing the order workflow to a more detailed sequence:

Processing → Picking → Packed → Staged → Shipped → Delivered

I decided not to replace the existing workflow because the current implementation was already working and tested. I felt that changing it at that stage would add complexity without providing enough additional value for the core requirements.

Instead, I kept the existing implementation and focused on making the application stable and easy to use.

2. Scope of the Application

AI suggested additional features such as automated courier recommendations, shipping-label integrations, barcode scanning, authentication and real-time marketplace integrations.

I chose not to implement all of them because the task focused on demonstrating my understanding of the fulfillment process and building a practical solution within the available time.

I prioritized the operational areas I considered most important for the given scenario:

Orders → Inventory → Warehouse Transfers → Issues → Couriers

This helped keep the application focused rather than adding features that were not essential to the core problem.

Reflection

AI helped me work faster during development, but I treated its suggestions as inputs rather than final decisions. I tested the application, evaluated suggestions against the actual business problem, and made the final implementation decisions myself.
